CLUB INFORMATIQUE & TÉLÉCOM

cat README.md

Presentation outline

1. Cryptography :
  - 1.1 notions
2. General :
  - 2.1 Encoding
    - 2.1.1 ASCII
    - 2.1.2 HEX
    - 2.1.3 Base64 / 32
  - 2.2 Caesar cipher / ROT13
  - 2.3 XOR

3. Challenges :

4. RSA :

5. Hashing :

# Warning !

*As we head through this meeting, we're gonna have some challenges for you to answer.. If you were able to solve one, please write **DONE** in the chat without writing the solution.*

*Don't spoil solutions on your friends :) !*

# Challenges

Challenge name : Back in Time

>> Find me.

**7wc0Fmcn52bD9VehN1XuF2QfV2Vfd3b09Vev9WW**

# Challenges

Challenge name : Scanner

*[+] my name is 64>>1*

**NB2HI4DTHIXS62LCMIXGG3ZPK5THARDDJBRQ**

# RSA

## Notions

*RSA, first described in 1977, is the most famous **public-key** cryptosystem.*

*It has two main use-cases:*

- ***Public key encryption** enables a user, Alice, to distribute a public key and others can use that public key to encrypt messages to her. Alice can then use her private key to decrypt the messages.*
- ***Digital signatures** enable Alice to use her private key to "sign" a message. Anyone can use Alice's public key to verify that the signature was created with her corresponding private key,.*

# Components

**n: decimal number (used in the modulo, must be big for more security)**

**e: exponent (must be  $\geq 3$ )**

**m: plain text**

**c: cipher text**

# Before we begin

Since the plaintext is a string (mostly), we must convert it to an integer so that it can be compatible with the arithmetic operations of the encryption, the ciphertext will also be an integer.

How ??

we'll go from base 256 to base 10

# Before we begin

Given the string "hello", we'll convert it from base 256 to base 10 as the following:

`ord('o')*(256**0)+ord('l')*(256**1)+...`

`ord` is a python function which gives the `ascii` number of a character.

**Yet!!** For a very long string, it's agony.

So there's a function in python called `bytes_to_long` in the library

`Crypto.Util.number` which does the same thing.

# Before we begin

Given the string "hello", we'll convert it from base 256 to base 10 as the following:

`ord('o')*(256**0)+ord('l')*(256**1)+...`

`ord` is a python function which gives the `ascii` number of a character.

**Yet!!** For a very long string, it's agony.

So there's a function in python called

`bytes_to_long` in the library

`Crypto.Util.number` which does the same thing. It's inverse is `long_to_bytes`.

# Encrypting

Suppose  $m = \text{"hello"}$

1- convert  $m$  to base 10

```
>>> ord('o')*256**0+ord('l')*256**1+ord('l')*256**2+ord('e')*256**3+ord('h')*256**4  
448378203247L
```

$m$  is now 448378203247

2- encrypting:

Given  $n$  and  $e$  (= public key):

$c = m^e \pmod n$  ( $m$  to the power of  $e$  modulo  $n$ )

$c$  is the cipher text and it's a decimal number

# Decrypting

Having  $c, e$  and the prime decomposition of  $n$  ( $p$  and  $q$  with  $n=p*q$ ), equivalent of **private key**.

1- calculate  $\phi=(p-1)*(q-1)$

2- compute the modular inverse of  $\phi$   
 $d$  with  $d*e=1[\phi]$

3- calculate  $m$ :

$m = c**d [n]$

4- convert  $m$  from base 10 to base 256:

using `Crypto.Util.number.long_to_bytes`

# Illegal Decrypting

Without knowing the prime decomposition of  $n$ , you can exploit a weak RSA encryption and find  $p$  and  $q$  by many attacks covered by **RsaCTFTool**

You can also be lucky and find the prime decomposition of  $n$  in **factordb**.

And also it depends on the situation, maybe you can have a relation between  $p$  and  $q$ , and therefore solving a second degree equation... It always depends.

# Implement w/ Python

❖ <https://lmgtyfy.app/?q=RSA>

# Hands on lab

Challenge : R-SAYYYY

>>

**n=88256459553622414063962598765941602942  
6239230804614613279163  
e = 65537  
cipher=348226401953293105681528097015649  
9240126029191801966285141813**

# HASHing

Hash is any function of encryption which can't be reversible.. There are many hashes as SHA1, SHA2, SHA256, SHA512, MD5, PKZIP, BCrypt,...

# HASHing

create a md5 hash :

```
echo -n "badboy" | md5sum
```

Crack the md5 hash :

**<https://crackstation.net/>**

shutdown
